Data Analysis

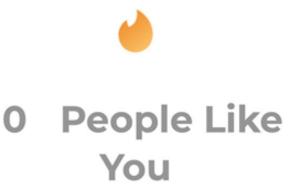

Model Evaluation

Facebook translates 'good morning' into 'attack them', leading to arrest

Palestinian man questioned by Israeli police after embarrassing mistranslation of caption under photo of him leaning against bulldozer

Model evaluation

- Offline evaluation; before deployed
 - Performance metrics (we covered these already!)
 - Error analysis
 - Bias/variance analysis
 - Robustness metrics
- Online evaluation: after deployed 7 th the reddy tin Refect, really after deployed let's Relie to Press

Test in production. We don't this discuss this for now

I trained a classifier with 80% accuracy. What's next? (>) [1]

Is flat feed 1

Add more data?

Add new features? 🗱 🔍

Performance baselines

- Numbers by themselves mean little
- Task: binary classification, 90% POSITIVE, 10% NEGATIVE
- F1 score: 0.90

Is the model good or bad?

Model selection: baselines new ve copie to Sigle routh

- Random baseline Synly in Clarify
 - Predict at random
 - uniform
 - following label distribution
- Zero rule baseline
 - Always predict the most common class
- Simple heuristics
 - e.g.: classify tweets based on whether they contain links to unreliable sources
- Human baseline Juge Per test Out
 - what's human-level performance?
- **Existing solutions**
 - E.g. out-of-the-box models etc.

- **Example:** misinformation classification
 - n = 1,000,000
 - 99% (990,000) negative (label = 0)
 - 1% (10,000) positive (label = 1)

	Accuracy	F1
Random [uniform]	0.5	0.02
Random [label distribution]	0.98	0.01
Most common [preds = [0] * n]	?	?
Simple heuristics	?	?
Human expert	?	?
3rd party API	?	? 6

Error analysis

- Error analysis systematically identifies the most common model errors.
 - 1. Collect a random subset of misclassified dev set examples.
 - 2. Manually examine them; identify the most common categories.
 - 3. Count \% of points affected by each error categories.
- You should prioritize the most common error categories.
- Error analysis involves classifying errors into categories.
 - A category is a systematic error made by the model.
 - Categories can come from intuition, but ideally they are constructed by manually examining the data.

Error analysis: An example

- Suppose you just trained a new image classifier.
 - After looking at the first 20-30 errors, you realize they are all due to images being either blurry, flipped, or mislabeled.
 - These become the error categories.

	Blurry	Flipped	Mis- labeled
lmg 1	X	X	
lmg 2		x	
Img 3			×
		•••	•••
Total	20%	50%	30%

- Real-world data is often messy and labels are not always correct
 - Scenario 1: 10% error, of which 0.4% is due to labeling and 9.6% to other causes. No need to relabel.
 - Scenario 2: 2% error, of which 0.4% is due to labeling and 1.6% to other causes. Important to relabel!

Error analysis but on what?

Would you do an error analysis on...:

- A. The training set?
- B. The validation set?
- D. The yellow unicorns from previous lectures?

, fle Convit de V

Bias/variance analysis

- Overfitting: A very expressive model fits the training dataset perfectly.
 The model makes incorrect predictions on the validation set (high variance)
- Underfitting: The model is too simple to fit the data well
 It is not accurate on training data and is not accurate on new data (high bias)
- Both are problematic:
 - High bias: Our model is not able to extract useful info from the data
 - High variance: Whatever the model picked up, it does not generalize to new data

Quantifying bias and variance

- Bias is simply the training error
- Variance is the extra error on the validation set
- We use these observations to diagnose bias/variance in practice
 - \circ High training error \rightarrow High bias
 - \circ High validation error \rightarrow High variance

OK, Over- or Under-fit?

Training error 15%

Validation error 16%

Human error 2%

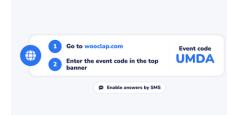

• Training error 4%

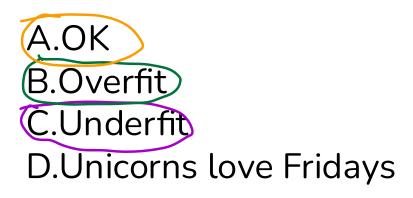

Validation error 12%

Human error 2%

Training error 2.5%
 Validation error 3%
 Human error 2%

Addressing variance Coulth

- Give the model more data 🗖 🗷 🖰 📶 🗸
- Drop or change features <a>S
- Reduce model size

Addressing bias

- Increase the expressivity (complexity) of the model b + 15 b
- Add or change features
- Adjust model architecture

Robustness methods

- 1. Perturbation Tests
- 2. Invariance Tests
- 3. Directional Expectation Tests
- 4. Model Calibration
- 5. Confidence Measurement
- 6. Slice-based Evaluation

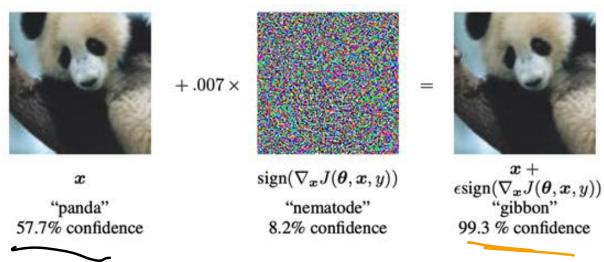

Perturbation tests

- Problem: users input might contain noise, making it different from test data
 - Examples:
 - Speech recognition: background noise
 - Object detection: different lighting
 - Text inputs: typos, intentional misspelling (e.g. looooooooong)
 - Model does well on test set, but fails in production

Afte on how People are Jona Vse it

Perturbation tests

- Motivation: users input might contain noise, making it different from test data
- Idea: randomly add small noise) to test data to see how much outputs change
- The more sensitive the model is to noise:
 - The harder it is to maintain
 - The more vulnerable the model is to adversarial attacks

gets Carpel

Perturbation tests 5 or 2 de Do

- Motivation: users input might contain noise, making it different from test data
- Idea: randomly add small noise to test data to see how much outputs change
- For tabular data:
 - 1. Select feature(s) to check
 - Define the perturbation strategy (e.g. random noise, value shifting/swapping, masking, outliers)
 - 3. Apply perturbation and check performance

If small changes cause model's performance to fluctuate, you might want to make model more robust:

- Add noise to training data
- Add more training data
- Choose another model

Invariance tests (also for fairness)

- Motivation: some input changes shouldn't lead to changes in outputs
 - Changing race/gender info shouldn't change predicted approval outcome
 - Changing name shouldn't affect resume screening results

The Berkeley study found that both face-to-face and online lenders rejected a total of 1.3 million creditworthy black and Latino applicants between 2008 and 2015. Researchers said they believe the applicants "would have been accepted had the applicant not been in these minority groups." That's because when they used the income and credit scores of the rejected applications but deleted the race identifiers, the mortgage application was accepted.

Invariance tests

- Motivation: some input changes shouldn't lead to changes in outputs
- **Idea**: keep certain features the same, but randomly change values of sensitive features

If changing sensitive features can change model's outputs, there might be biases!

Directional expectation tests

- Motivation: some changes to inputs should cause predictable changes in outputs
 - E.g. when predicting housing prices:
 - Increasing lot size shouldn't decrease the predicted price
 - Decreasing square footage shouldn't increase the predicted price
- Idea: keep most features the same, but change certain features to see if outputs change predictably

If increasing lot size consistently reduces the predicted price, you might want to investigate why!

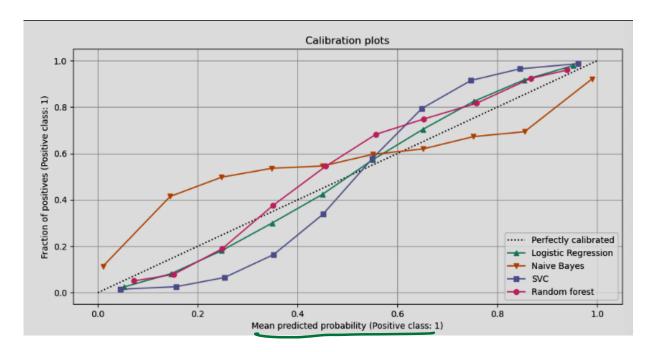

Model calibration

- If you predict team A wins in A vs. B match with 60% probability:
 - o In 100 A vs. B match, A should win 60% of the time!

wehre the Espect that longer between the 2

Model calibration: binary case

Among all samples predicted POSITIVE with probability 80%, 80% of them should be POSITIVE

Model calibration: recsys

- Recommend movies to a user who watches 70% comedy, 30% action
- What happens if you recommend most likely watched movies?

Need to calibrate recommendations to include 70% comedy, 30% action

Movie title	Watch probability
Comedy 1	0.8
Comedy 2	0.73
Comedy 3	0.68
Comedy 4	0.67
Action 1	0.29
Action 2	0.2
Science fiction	0.04

Confidence measurement

- Usefulness threshold for each individual prediction
- Uncertain predictions can cause annoyance & catastrophic consequences

- How to measure the confidence level of each prediction?
 - Probability distribution (e.g. logistic regression or softmax)
 - Margin of Confidence (difference between the 2 probabilities)
 - More advanced methods (e.g. conformal prediction)
- What to do with predictions below the confidence threshold?
 - Skip
 - Ask for more information
 - Loop in humans

Slice-based evaluation

Different performance on different slices

- Classes
 - Might perform worse on minority classes
- Subgroups
 - Gender
 - Location
 - Time of using the app
 - o etc.

Same performance on different slices with different cost

- User churn prediction (i.e. when a customer stops engaging with a service)
 - Paying users are more critical
- Predicting adverse drug reactions
 - Patients with underlying conditions are more critical

 Δ Focusing on improving only overall metrics might hurt performance on subgroups Δ

Slice-based evaluation: example

Majority group: 90%

• Minority group: 10%

Coarse-grained evaluation can hide:

- model biases
- potential for improvement

	Majority accuracy	Minority accuracy	Overall accuracy
Model A	98%	80%	96.2%
Model B	95%	95%	95%

Simpson's paradox

- Models A and B to predict whether a customer will buy your product
- A performs better than B overall
- B performs better than A on both female & male customers

Simpson's paradox

	Treatment 1	Treatment 2
Group A	93% (81/87)	87% (234/270)
Group B	73% (192/263)	69% (55/80)
Overall	78% (273/350)	83% (289/350)

Slice-based evaluation

- Evaluate your model on different slices
 - E.g. when working with website traffic data, slice data among:
 - gender
 - mobile vs. desktop
 - browser
 - location
- Check for consistency over time
 - E.g. evaluate your model on data slices from each day
- Improve model's performance both overall and on critical data
- Help avoid biases
- Even when you don't think slices matter, slicing can:
 - give you confidence on your model (to convince your boss)
 - might reveal non-ML problems

How to identify slices?

- Heuristics
 - Might require subject matter expertise (consult domain experts)
- Error analysis
 - Patterns among misclassified samples
- Slice finder (i.e. use a model)
 - Exhaustive/beam search
 - Clustering
 - 0 ...

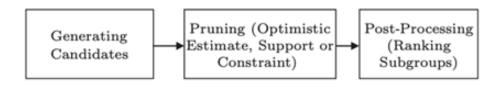

Fig.1. Methodology for subgroup discovery.
